

## **RFID-Solution for Optimizing the Logistic of an Assembly Line for Agricultural Machinery**

M. Baldinger<sup>1</sup>

### **Summary**

The aim of this paper is to demonstrate how the new highest technology can be used to develop and optimize the manufacturing plant. Based on the results of a preliminary study and other observations made during the last year, it was decided to bring a new technology in its factory. On the basis of climbing demand and the ever bigger nascent variety with the production of self loading wagons, the machine-factory is modernized by a mounting-street for self loading wagons. The use of RFID-technology, tied into an ERP-System, led to a clear optimization of the production-process.

### **Introduction**

An elevated transparency, a current feedback of the assembly advance and a preparation of reliable production data are the catch phases for an efficient assembly line. In the framework of the rebuilding of the assembly line of the self loading wagons, an initiative was started to the optimization of the job-referential production of different loading wagons. Concretely, following goals were pursued with this initiative:

- An elevated transparency along the production-process
- A current feedback of the current production- and assembly-advance
- A preparation of reliable production-data for the sale - and shipping-department
- A focusing of the worker on the assembly-activities

In combination with an Intranet as well as Internet link, there will be an easy operation and administration of the system. Comparing the costs as well as the savings of such an example in dependence of the increase of the productivity, the investigation of such a system calculates itself.

To this purpose, an automated data-recording was required in the production. A touch-less RFID-technology (radio frequency identification) should come to use.

### **Initial situation**

The purpose of the use of a RFID-system at the assembly line is the documentation of the production-advance and in further consequence a production-near, automated advance-degree-booking during the assembling of the self loading wagons.

In the existing situation, an entire production-job of a self-loading wagon is dispatched into the ERP-System and the parts for the assembling will be reserved in the store. Parts, that would be required also at other assembly lines for further

---

<sup>1</sup>Alois Pöttinger Maschinenfabrik GmbH., Industriegelände 1, 4710 Grieskirchen, Austria

products, cannot be accessed by the reservation of the total of a production-job. The back posting of the manufactured self loading wagon takes place intermittently at the end of the assembly line and the stock will be updated.

The RFID-technology should deliver a production-near back posting of the production-advance to the ERP-System with a discharge of the stock in dependence to the actual production-step.

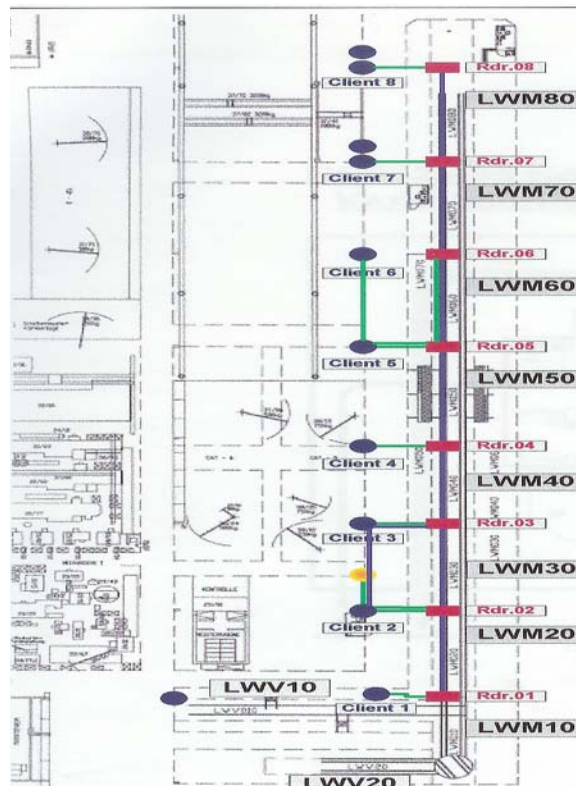

Figure 1: Layout of the assembly line

### General survey - system solutions

In the first workstation of the assembly line, the self loading wagons are equipped with a RFID-transponder, on which the job-number is stored. On the basis of the predominate environment-conditions and to the guarantee of a long durability, special capsuled synthetic resin transponders were used. They are optimally placed on the self loading wagon on the one hand and offer a high mechanical, chemical and thermal constancy on the other hand. The attachment takes place over clip-mountings, so that a quick fastening can be enabled on the self loading wagon. Over this transponder, the self loading wagon is unequivocally marked and can be

identified contactless and fully automatically.

Figure 2: Progressing processes

RFID-reader and –writer are installed on the individual assembly stations, whereas the antennas are brought in into the ground. The self loading wagons go through the assembly-stations sequential afterwards.

In figure 3, one can see the detailed planning of machines. This will be dispatched by the first assembly station. The date classification is done by the customer.

Figure 3: Stock of machines

As soon as the self loading wagon comes in into one of the assembly stations, it is identified automatically over the transponder and the job order-number will be reported to the ERP system. Therefore it is deposited, which self loading wagon is to which time at which station.

The worker receives all necessary information over work-steps and mounting parts on a display automatically, see figure 4.

The screenshot displays the SAP Montageplatzpool interface. On the left, a tree view shows the hierarchy of assembly stations (Montageplatz) under 'Montage LW'. The main area shows a detailed list of parts (Montageplatzstückliste) for a specific station. The table includes columns for 'Bezeichnung', 'GorB', and 'BedMenge'. The parts listed include various mechanical components like 'LASTSICHERUNGSBAND', 'SCHNALLE', 'STÄFFEL', 'FEDERVORSTECHE', 'Spannstift', 'ABDECKPLANE', 'SEIL MIT 2 OEBEN', 'Bügel II SZ lackiert', 'Traktorkabel ISO', 'Bedienfeld Power Control', 'Monitorhalterung', 'Lackische SZ', 'Saughafter Ø120mm', 'SK-SCHRAUBE M 6x 20 DIN 933', 'SICHERUNGSMUTTER M 6 DIN 9...', 'DECKSCHIBE ST1203 KAUFF...', 'Bügel II SZ', 'Radträger II SZ', 'BEREIFUNG 16/6 50-8 GPR, RP M...', 'Spannstift 8 x 45-DIN 1481-Dac...', 'SCHEIBE 13,00 / 30 X 5,00 ST 36...', 'SCHEIBE 25,20 / 34 X 2,00 ST 36...', 'SCHEIBE 30,20 / 50 x 3 ST3608 C...', 'SCHMIERKUPPEL DIN 71412 A.M.', 'RADKAPPE D.52', 'OMNIFIT M 100 SPEZIAL 250 CCM', 'DECKSCHIBE ST1203 KAUFF...', 'Bügel lackiert', and 'Montageplatz LVM0080'.

Figure 4: Assembly station pool

Also drawings can be represented on the display.

As soon as the worker has performed his activities, the self loading wagon leaves the assembly station. This also becomes detected through the RFID transponder and an automatic debit of the object list in the ERP-system is nudged. Possible deviations are corrected manually by the worker.

Still, also the run-time is measured over the radio frequency identification system in the individual assembly workstation, that is drawn near for statistical evaluations and optimization-measures.

### Conclusion

An advanced management approach including contactless identification is extended with the highest technical standards. The system solution was presented and explained by means of different views. The repertoire is concluded by the possibility of the viewing of the mounted parts. The accessibility to existing databases automatized in full brings the data afterwards directly into the ERP-system without any expenditure. Also the integration into an intranet as well as the application of a automatic post mortem analysis refer to a further important milestone into a fully automated solution.

One can summarize:

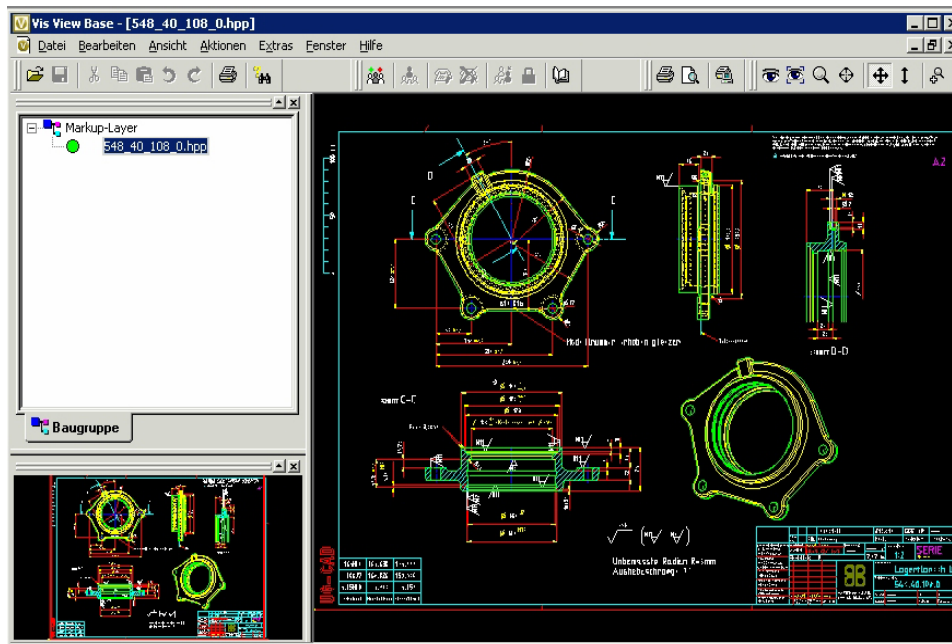

Figure 5: Viewing picture

- Automatic reply of the degree of production in real-time
- Updating of the actual stock in real-time
- High level of transparency and retraceability
- Increase of availability of the parts through an actual stock
- Statistical evaluations for machining and cycle time

Put together, the proposed approach may lead to an optimal assembly process control program, based upon specific solutions such as connection between to different sub systems (ERP and stand alone software), Integration into existing software and the use of the newest technique on the sector of RFID.
